CSSE3100 Crib Sheet

Collection Types

Arrays

Arrays are a mutable collection of elements stored on the heap.

For an array, a, to be modified by a method, it must include modifies a in the specification.

Type array<T> Type array<7>
Creation var a := new T[length] immutable. Accessing var value := a[i]; Assigning a[i] := value; Alias var b := a; Length var 1 := a.Length;

Multi-dimensional Arrays

```
Type array<array<...<arrayisteenee var u := s - t;
Creation var a := new T[11, 12Contains blem in s:
Accessing var value := a[i1, i2Excludes idlem !in s;
Asigning a[i1, i2, ..., iN] := Distoint elem !! s;
   Alias var b := a;
 Length (11, 12, ..., 1N) : Specification Keywords
                 a.Length2, RequirementhN);
```

Sequences

Sequences are used to represent an ordered list. They are immutable. Type seq<T>

Length var 1 := |s|; Slicing var t := a[start...Madifies Appending var u := s + t; Contains value in s;

Sets

Sets are used to represent an orderless collection of elements, without repetition. Sets are immutable.

Excludes value !in s:

```
Type set<T>
                                Invariant
     Creation var s := \{x1, x2, \ldots, xN\};
     Equality \{x1, x2\} == \{x2, A_1\} hvariant clause stipulates
                       {x1, x1 a condition I which must be
       Subset s <= t
                                true at the beginning and end
Proper Subset s < t
                                of a loop.
        Union var u := s + t;
  Intersection var u := s * t;
```

Excludes elem !in s:

Contains elem in s;

Multisets

Multisets are used to

represent an orderless

collection of elements, with

Type multiset<T>

Union var u := s + t;

Difference var u := s - t; Decreases

A decreases clause indicates a value D which decreases after every iteration of a loop.

Question 1

Forall

A forall clause is used to stipulate that a condition Q must hold for all values of a Creation var s := multiset{x iven variable. For example, From seq var s := multiset([xirall·i xN]) [i] ==> Q[i] From set var s := multiset({xiquires Q[X]}) to hold for all Slicing var s: seq<T> := a[startahitenthitiset{x1, x2} ==values of i where P[i] holds. multiset{x2, x1} != multiset{x1, x1, x2, x2}; Exists

An exists clause is used to

exists i :: P[i] ==> Q[i] requires Q[i] to hold for at least one value of i where P[i] holds.

Ensures

method.

A requires clause stipulates a Creation var s := [x1, x2, condition; R which must be Accessing var value := s[i]; true when exiting the method.

A requires clause stipulates a

condition P which must be

true upon entry to the

A modifies clause is required if a method changes a value on the heap (i.e. a value in an array is changed).

Reads

A reads clause is required if a method reads a value on the heap (i.e. a value in an array is read).

stipulate that a condition Q must hold for at least one value of a given variable. For example.

Fresh

Fresh is used to indicate that a value stored on the heap must be brand new with no modifications. For example, fresh(x) requires x to be a brand new value on the heap.

Old

Old is used to reference the value on the heap before the method began. For example, old(a[i]) refers to the element at index i at the beginning of the method.

```

Replace a constant by a variable

}

}

For a loop to establish a condition P(C), where C is an expression that is held constant throughout the loop, use a variable k that the loop changes until it equals C, and make P(k) a loop invariant. For example, Min method (Week 4) had postcondition

s := s + 2*r + 3;

r := r + 1;

==> m <= a[i]

and invariant

invariant forall i :: 0 \leftarrow termination metric for a ==> m <= a[i]

What's yet to be done

. If you're trying to solve a problem of the form p ==F(n), replacement of a constant by a variable results in a what-has-been-done invariant

invariant p == F(i)

Alternatively, you may use a what's-vet-to-be-done invariant

invariant p @ F(n - i)

where @ is some kind of combination operation.

Use the postcondition

To establish a postcondition Q, make Q a loop invariant. For the Min example, to ensure the postcondiVon

used as a termination metric. An order \succ is well-founded when

- \succ is irreflexive: $a \succ a$ never holds
- $\bullet \succ$ is transitive: $a \succ b \&\& b \succ c \Longrightarrow$ $a \succ c$
- there is no infinite descending chain $a_1 \succ a_2 \succ a_3 \succ \dots$

We write X decreases to x as $X \succ x$. For integers, $X \succ x$ when

ensures forall i :: $0 \le x \le x \in x = 0$.

For booleans, $X \succ x$ when X

recursive function is a metric that can be proven to decrease every iteration. E.g. for the function;

> function F(x: int): int if x < 10 then x els@Esses 1)

the termination metric would be x since $x \succ x - 1$.

Lexicographic tuples

A lexicographic order is a component-wise comparison =\overline{\pi}\earlier components are more significant.

$$\{a_0, a_1, a_2, \dots, a_n\} \succ \{b_0, b_2, b_3, \dots, b_n\} \text{ if and only if}$$
 $a_0 \succ b_0 \mid\mid (a_0 == b_0 \&\& a_1 \succ b_1) \mid\mid (a_0 == b_0 \&\& a_1 == b_1 \&\& a_2 \succ b_2) \mid\mid \dots \mid\mid$

• have class invariant. ghost predicate Valid()

 $a_{n-1} == b_{n-1} \&\& a_n > b_n$

Mutually Recursive Functions

Tuples can be used to provide

values that the functions may

termination metrics.

E.g. for the following

}

}

reduce on $1 \succ 0$.

Simple Classes

else {

the termination matrix would

be $\{i, 1\}$ for H and $\{i, 0\}$ for

F since the call F(i) in H will

Ghost variables can be used

ghost var d: T

A simple class consits of only

The specification for a simple

• ghost variables for

abstract state

simple object, (i.e. objects

that are not stored on the

for specification and reasoning

r := 1 + h:

if $i == 0 \{ r := 0;$

r := f + h:

var f := F(i);

reduce on.

methods:

- Valid() and functions have reads this
- constructor has ensures Valid()
- methods have **requires** Valid(), modifies this, ensures Valid()

Concrete states that consist of only simple objects are method F(i: nat) returns created and are related to the if i <= 2 { r := 1; abstract state in Valid(). The constructor, methods, var h := H(i - 2) functions must satisfy the class specification and will require both concrete and abstract state to be updated.

Complex Classes

method H(i: nat) returns (r: nat) { complex classes consist of any combination of simple and complex objects, (i.e. objects that are stored on the heap). var h := H(i - 1 complex classes require a representation set,

Invariant

The invariant valid will consist of the following, where a, a0, a1 are non-composite objects or arrays and b, b0, b1 are composite objects.

```
ghost predicate Valid()
    reads this, Repr
    this in Repr && ...
```

For an array **a**, include:

a in Repr

For two identically typed arrays **a0**, **a1**, include;

a0 != a1

For a non-composite object **b**, Lemmas can be called in a include:

b in Repr && b.Valid()

For two identically typed non-composite objects b0, **b1**. include:

include;

Constructor

object **b**.

For a composite object \mathbf{c} . include;

method to **prove** the lemmas property from that point onwards.

Calc

To prove a lemma by hand. you can add a calc section into the lemmas body, where γ is the default transitive operator between lines.

```
c in Repr && c.Repr <= Repr c&& {
    this !in c.Repr && c.Valid()
                                      5 * (x + 3);
                                      == 5 * x + 5 * 3;
For a composite objects c0,
                                      == 5x + 15;
c1 and non-composite objects
and arrays a0, a1, b0, b1,
```

You can use use any transitive {a0, a1, b0, b1} !! c0. Reperator between lines (e.g. ==>). If no default operator is specified, the default is ==. For a non-composite array or The calc statements can also object **a** and a composite be added inline within a

method instead of creating and calling a lemma. constructor() ensures Valid() && fresh(Repro)ion ensures ... (initial abstract state) Lemmas can also be used to

... (initialise concrete plane doing industion by recursively calling the lemma ghost var Repr: set<object> new; Repr := {this, a, b} + binebe:body. E.g.

```
